1 Introduction. Monoterpenoid indole alkaloids (MIAs) constitute the largest and most heterogeneous group of nitrogen-containing secondary metabolites among this class of compounds, and they are widely distributed within the Apocynaceae, Loganiaceae, and Rubiaceae plant families. Their complex synthesis involves the assembly of tryptamine with a secoiridoid to produce the central intermediate, strictosidine, which can be converted by a range of oxidative, substitution, and rearrangement ...

Indole Alkaloids: An Introduction to the Enamine Chemistry ...

This chapter discusses the origin of indole alkaloids. The classical view of the origin of the indole alkaloids was predicated almost entirely upon the structure of a single alkaloid yohimbine. This alkaloid was considered to stem from tryptophan, phenylalanine, or its equivalent and formaldehyde via two Mannich condensations.

Monoterpenoid Indole Alkaloid - an overview ...

Indole is an aromatic heterocyclic organic compound with formula C8H7N. It has a bicyclic structure, consisting of a six-membered benzene ring fused to a five-membered pyrrole ring. Indole is widely distributed in the natural environment and can be produced by a variety of bacteria. As an intercellular signal molecule, indole regulates various aspects of bacterial physiology, including spore formation, plasmid stability, resistance to drugs, biofilm formation, and virulence. The amino acid trypt

Indole - Wikipedia

Alkaloids are a special group of secondary compounds and are part of an organism's adaptation mechanism to its living environment. They are not toxic when stored, but become toxic as a result of cell pH change. The defensive function of alkaloids is only secondary, and connected to internal immune and regulation processes.
